Not illustrated. 1918 Excerpt: .curves, whose ordinates lie halfway between those of the two sides of the hysteresis loops.--Trans. They pass through the tips of the loops, and depend on the maximum amount to which the stress has been raised, or, in practice, upon the Fig. 61.--Test IX Hysteresis loops for the shear characteristic (fabric G). excess stresses encountered by the envelope during flight. Since the stresses occurring in practice are decidedly less than the critical stress (that which produces folds) only the central part of the curve is of importance. If now we go over into three dimensions and for each value of the shearing stress plot a surface representing the shear as a function of the longitudinal and of the lateral tension, the family of surfaces so produced forms the shear characteristic in the form described on page 190. Now in figure 61 we see that for slight shearing stresses the average curves are very approximately straight lines, so that within certain limits Hooke's law applies. We may then reduce the shear characteristic to a single surface by plotting the slope of this line, or modulus of shear, as a function of the tensions. The slope taken is that at the point of inflection in the curve. The graph is in figure 62. For example: From loop No. 1 we find the value of the modulus of shear to be  $10 \times 127.5 = 1275$  kg/m for  $\sigma_1 = 300$  and  $\sigma_2 = 240$ , and this value...
